6.001 SICP Variations on a Scheme

- Scheme Evaluator a Grand Tour
 - Make the environment model concrete
 - · Defining eval defines the language
 - Provide a mechanism for unwinding abstractions
- · Techniques for language design:
 - Interpretation: eval/apply
 - · Semantics vs. syntax
 - Syntactic transformations
- Beyond Scheme designing language variants
 - Today: Lexical scoping vs. Dynamic scoping
 - · Next time: Eager evaluation vs. Lazy evaluation

Last Lecture

- Last time, we built up an interpreter for a new language,
 - Conditionals (if*)
 - Names (define*)
 - · Applications
 - · Primitive procedures
 - Compound procedures (lambda*)
- Everything still works if you delete the stars from the names.
 - So we actually wrote (most of) a Scheme interpreter in Scheme.
 - · Seriously nerdly, eh?

,

Today's Lecture: the Metacircular Evaluator

- Today we'll look at a complete Scheme interpreter written in Scheme
- Why?
 - · An interpreter makes things explicit
 - e.g., procedures and procedure application in the environment model
 - Provides a precise definition for what the Scheme language means
 - Describing a process in a computer language forces precision and completeness
 - · Sets the foundation for exploring variants of Scheme
 - Today: lexical vs. dynamic scoping
 - Next time: eager vs. lazy evaluation

3/40

- Core evaluator
 - eval: evaluate expression by dispatching on type
 - apply: apply procedure to argument values by evaluating procedure body

4/40

Side comment - procedure body

 The procedure body is a sequence of one or more expressions:

```
(define (foo x)
  (do-something (+ x 1))
  (* x 5))
```

• In m-apply, we eval-sequence the procedure body.

12/40

14/40

Pieces of Eval&Apply

13/40

15/40

Pieces of Eval&Apply

Pieces of Eval&Apply

2

```
Pieces of Eval&Apply

(define (eval-if exp env)
   (if [m-eval (if-predicate exp) env)
        (m-eval (if-consequent exp) env)
        (m-eval (if-alternative exp) env)))
```

2. syntax procedures 9. What the language means 9. Model of computation 9. Syntax 9. Particulars of writing expressions 9. E.g. how to signal different expressions 9. Separation of syntax and semantics: allows one to easily alter syntax | Syntax |

```
Basic Syntax

(define (tagged-list? exp tag)
    (and (pair? exp) (eq? (car exp) tag)))

• Routines to detect expressions
(define (if? exp) (tagged-list? exp 'if))
(define (lambda? exp) (tagged-list? exp 'lambda))
(define (application? exp) (pair? exp))

• Routines to get information out of expressions
(define (operator app) (car app))
(define (operands app) (cdr app))

• Routines to manipulate expressions
(define (no-operands? args) (null? args))
(define (first-operand args) (car args))
(define (rest-operands args) (cdr args))
```

```
Implementing "Syntactic Sugar"

• Idea:

• Easy way to add alternative/convenient syntax

• Allows us to implement a simpler "core" in the evaluator, and support the alternative syntax by translating it into core syntax

• "let" as sugared procedure application:

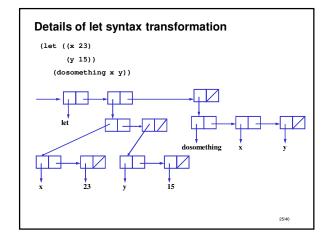

(let ((<name1> <val1>) (<name2> <val2>)) <body>)

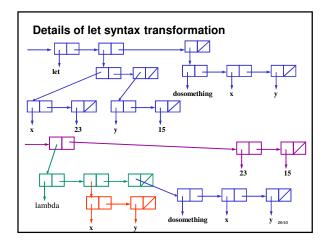

((lambda (<name1> <name2>) <body>)

<val1> <val2>)
```

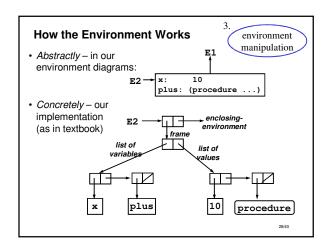

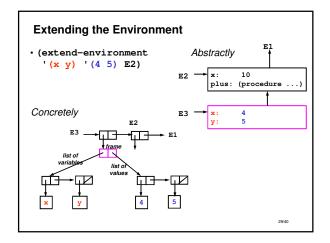

```
Let Syntax Transformation
(define (let? exp) (tagged-list? exp 'let))
(define (let-bound-variables let-exp)
  (map car (cadr let-exp)))
(define (let-values let-exp)
  (map cadr (cadr let-exp)))
(define (let-body let-exp)
  (cddr let-exp))
(define (let->combination let-exp)
 (let ((names (let-bound-variables let-exp))
        (values (let-values let-exp)
        (body (let-body let-exp)))
                                      NOTE: only manipulates list
    (cons (make-lambda names body)
                                       structure, returning new list
                                       structure that acts as an
          values)))
                                       expression
```

```
Defining Procedures
 (define foo (lambda (x) <body>))
 (define (foo x) <body>)
  Semantic implementation – just another define:
(define (eval-definition exp env)
  (define-variable! (definition-variable exp)
                   (m-eval (definition-value exp) env)
                   env))
  Syntactic transformation:
(define (definition-value exp)
  (if (symbol? (cadr exp))
      (caddr exp)
      (make-lambda (cdadr exp)
                                     ;formal params
                     (cddr exp))))
                                     ; body
                                                      27/40
```

"Scanning" the environment

- · Look for a variable in the environment...
 - Look for a variable in a frame...
 - loop through the list of vars and list of vals in parallel
 - detect if the variable is found in the frame
 - If not found in frame (i.e. we reached end of list of vars), look in enclosing environment

30/40

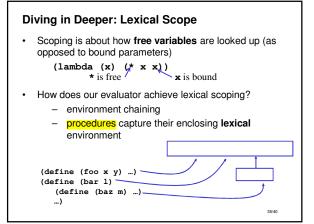

```
The Initial (Global) Environment
                                                primitives and
                                                  initial env.
· setup-environment
  (define (setup-environment)
    (let ((initial-env (extend-environment
                            (\verb"primitive-procedure-names")
                            (primitive-procedure-objects)
                           the-empty-environment)))
      (define-variable! 'true #T initial-env)
      (define-variable! 'false #F initial-env)
      initial-env))
· define initial variables we always want
· bind explicit set of "primitive procedures"
   · here: use underlying Scheme procedures
   • in other interpreters: assembly code, hardware, ....
                                                         32/40
```

```
Read-Eval-Print Loop

(define (driver-loop)
   (prompt-for-input input-prompt)
   (let ((input (read)))
        (announce-output output-prompt)
        (display output)))
   (driver-loop))
```

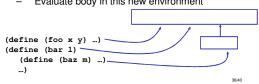

Variations on a Scheme

- More (not-so) stupid syntactic tricks
 - · Let with sequencing (let* ((x 4) (y (+ x 1))) . . .) Infix notation ((4 * 3) + 7) instead of (+ (* 4 3) 7)
- · Semantic variations
 - · Lexical vs dynamic scoping
 - -Lexical: defined by the program text
 - Dynamic: defined by the runtime behavior

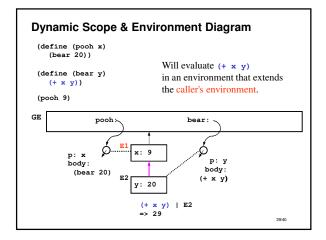

Diving in Deeper: Lexical Scope

- Why is our language lexically scoped? Because of the semantic rules we use for procedure application:
 - "Drop a new frame"
 - "Bind parameters to actual args in the new frame"
 - "Link frame to the environment in which the procedure was defined" (i.e., the environment surrounding the procedure in the program text)
 - "Evaluate body in this new environment"

Lexical Scope & Environment Diagram (define (foo x y) (lambda (z) (+ x y z))) Will always evaluate (+ x y z) (define bar (foo 1 2)) in a new environment inside the surrounding lexical environment. (bar 3) foo: (λ (z) 37/40

Alternative Model: Dynamic Scoping · Dynamic scope: - Look up free variables in the caller's environment rather than the surrounding lexical environment Suppose we use our usual environment model rules... · Example: bear (define (pooh x) (bear 20)) (define (bear y) (+ x y)) p: x b: (bear 20) (pooh 9) x: 9 y: 20 (bear 20) (+ x y) x not found -

Summary

- Scheme Evaluator Know it Inside & Out
- Techniques for language design:
 - · Interpretation: eval/apply
 - · Semantics vs. syntax
 - · Syntactic transformations
- Able to design new language variants!
 - · Lexical scoping vs. Dynamic scoping
